

## Antifungal Activity of Extracts of *Euphorbia Kamerunica* PAX

Ogunnusi, T.A

Department of Biological Sciences, College of Science, Afe Babalola University, Ado- Ekiti, Nigeria

---

**Abstract:** Antifungal activities were detected in crude extracts of *Euphorbia kamerunica* plant using different organic solvents and water. Radial growth was used to measure the activity. Growths were observed only at concentrations of 2.5 mg/ml and 5 mg/ml and not at 10 – 100 mg/ml. Ethyl acetate extract inhibited the growth of *Microsporium audouinii* for the entire period of the experiment (9 days) even at 2.5mg/ml. There were decreases in radial growths with increases in concentration of extracts hexane, aqueous and methanol extracts on *Aspergillus niger*. Ethanol extract inhibited the growth of *Microsporium canis* var. *distortum* until day 7 at 2.5 mg/ml and 5 mg/ml with radial growth being 14.0±0.0g. Fungi used included *Aspergillus niger*, *Aspergillus flavus*, *Microsporium audouinii*, *Microsporium canis* var. *distortum* and *Trichophyton mentagrophytes* var. *nodulare*.

**Keywords:** Antifungal activity, crude extract, dermatophytes, *Euphorbia kamerunica*, organic solvents.

---

### I. Introduction

*Euphorbia kamerunica* plant belongs to the family Euphorbiaceae and plants in this family have been used to treat skin infections such as ulcers, warts, cancers, tumors [1,2,3,4]. The plant is known to contain skin irritants, co-carcinogenic principles and other toxic constituents responsible for health hazards to both human and grazing livestock [5] with its bioactivity on brine shrimp (*Artemia salina*) investigated [6]. Extract from *Euphorbia* species have been used in the treatment of skin diseases, migraine and intestinal parasites and warts [7]. Plants belonging to the family Euphorbiaceae have been found to contain diterpenes which have tigliane, ingenane and daphnane skeletons [8].

Medicinal plants have been used in the treatment of different diseases including skin diseases such as mycotic infections which is an old age practice in different parts of the world [9]. Compounds from plant extracts which are secondary metabolites serves as defence agents against invading microorganisms [10].

Researchers have conducted studies on antifungal substances from plants [11] which include terpenes, tannins, alkaloids, steroids, saponins, phenols, quinines and flavonoids. A great number of antimicrobial agents already exist for various purposes but the search for new antimicrobials ought to continue since the target microorganisms often evolve into new genetic variants which subsequently become resistant to existing agents with the current trend in the biotechnology of plant tissue cultures [12].

Dermatomycoses are infections produced by dermatophytes and may not be common as other microbes but when present, they could be difficult to eradicate especially in immunosuppressive situations. There are currently emergence of resistance strains and drug toxicity. Therefore, there is a distinct need for the discovery of new, safer and more effective antifungal agents [13]. New topical agents that will be effective are needed since fungal infections are difficult to treat even with the use of antifungal drugs [14] with drawbacks of major antibiotics being increase in incidence of opportunistic mycoses associated with AIDS.

*Trichophyton*, *Microsporium* and *Epidermophyton* are causative agents of dermatophytoses implicated in infections of the hair, skin and nails [15,16,17,18]. The ability to invade keratinized tissues and possession of several enzymes, such as proteinases, elastases, keratinases and other proteinases are the major virulence of these fungi [19] while *Aspergillus flavus* is implicated in invasive disease of immunosuppressed patients.

The investigation of plants used in traditional medicine for skin infections might also provide new topical antiseptic urgently needed in the third world countries. The actinomycotic activity of higher plants remained largely unexplored when compared with that of other microorganisms. In Nigeria, herbal remedies are still the preferred and sought method in the treatment of various ailments especially among the rural dwellers. The objective of this present work is to determine the antifungal activity of this plant extracts on some pathogenic fungi.

### II. Materials and Methods

#### 2.1 Plant material and extraction

*Euphorbia kamerunica* plant was collected from the Botanical Gardens of the University of Ibadan, Oyo state, Nigeria and authenticated by Prof Biodun Ayodele of the Department of Botany, University of Ibadan. A voucher specimen with no 22278 was deposited at the herbarium. The plant was washed, cut and pounded into pulp using a mortar and pestle and extraction was carried out using the soxhlet apparatus. Solvents

used included hexane, dichloromethane, diethyl ether, ethyl acetate, methanol, ethanol, acetone and water. The extracts were then filtered and evaporated to dryness under reduced pressure and kept in the refrigerator until needed.

## 2.2 Microorganisms and medium.

*Aspergillus niger* and *Aspergillus flavus* were obtained from the Department of Botany and Microbiology, University of Ibadan and they were grown at 30°C and maintained at 4°C on Potato dextrose agar (PDA) slants. The dermatophytes used were *Trichophyton mentagrophytes* var. *nodulare*, *Microsporum canis* var. *distortum* and *M. audouinii*. They were grown at 30°C and maintained at 4°C on Sabouraud dextrose agar (SDA) slants.

## 2.3 Preliminary phytochemical studies.

Preliminary phytochemical studies were carried out using the methods described by [20] and [21]. Basic phytochemical screenings were performed on ethyl acetate and methanol extracts to test for alkaloids, phenols, chalcones, saponins, cardiac glycosides, flavonoids, tannins, anthraquinones and combined anthraquinones.

## 2.4 Antifungal assay

The methods of [22] and [23] were used. The extracts were tested on *Microsporum audouinii*, *Microsporum canis* var. *distortum*, *Trichophyton mentagrophytes* var. *nodulare*, *Aspergillus niger*, and *Aspergillus flavus*. With the aid of a sterile 9.0 mm cork borer, mycelial discs were cut from 7- day old cultures of dermatophytes and fungi and aseptically transferred to the centre of Petri dishes containing Sabouraud dextrose agar for dermatophytes and Potato dextrose agar for fungi impregnated with different concentrations of the extracts- 2.5, 5.0, 10.0, 25.0, 50.0 and 100.0mg/ml. Agar plates without extracts similarly inoculated with mycelial disc of test dermatophytes and fungi served as control. The plates were incubated in duplicates at 30°C and radial growth was measured daily for nine days in two directions and the mean calculated to assess the antifungal property of the extract at different concentrations. The experiment was carried out in duplicates.

## 2.5 Statistical analysis

Results were expressed as means  $\pm$  S.D of two separate experiments. Statistical significance was determined using SPSS 10 software after one-way variance analysis.

## III. Results and discussion

Seven extracts of *Euphorbia kamerunica* were obtained using different solvents- hexane, ethyl acetate, acetone, aqueous, methanol, ethanol and dichloromethane. The activities of these extracts at different concentrations were tested on *Aspergillus flavus*, *Aspergillus niger*, *Microsporum audouinii*, *Microsporum canis* var. *distortum* and *Trichophyton mentagrophytes* var. *nodular*. Extracts of *Euphorbia kamerunica* when screened contained alkaloids, phenols, chalcones, saponins, cardiac glycosides, flavonoids and tannins. Phlobatannins, anthraquinones and combined anthraquinones were found to be absent in the plant extracts used (result not shown).

TABLE 1 shows the effect of crude extracts of *E. kamerunica* using different solvents on the radial growth of *Aspergillus niger*. At concentrations of 10.0, 25.0, 50.0 and 100.0 mg/ml, the extracts inhibited the growth of the fungus. At 2.5 mg/ml and 5.0 mg/ml, growths were observed. After 24 hours of incubation, the radial growth of the control was  $16.5 \pm 2.0$  mm. Hexane extract at concentration of 2.5mg/ml and aqueous extract at concentrations of 2.5 mg/ml and 5.0 mg/ml had radial growths which were  $13.5 \pm 0.5$  mm,  $15.5 \pm 5.0$  mm and  $15.0 \pm 2.0$  mm respectively. There were no significant differences in these values. The extracts were not effective. Dichloromethane extract at 2.5mg/ml and 5.0mg/ml inhibited the growth of *A. niger* till day 3 while growth was observed on day 4. At concentration of 2.5mg/ml on day 4, the growth was  $21.5 \pm 2.5$  mm and  $21.5 \pm 2.5$  mm at 5.0mg/ml and compared to the control, these values were significantly different.

Diethyl ether extract gave the least growth on day 9. At concentration of 5.0mg/ml, the growth was  $39.5 \pm 2.5$  mm and  $55.5 \pm 1.5$  mm at 2.5 mg/ml, while for methanol extract on the same day, at concentration of 2.5 mg/ml the radial growth was  $48.0 \pm 0.0$  mm and  $41 \pm 1.0$  mm at 5.0 mg/ml and these values were not significantly different from each other but to the control value, they were significantly different. The value of the radial growth of hexane extract at concentration of 2.5 mg/ml was  $90.0 \pm 0.0$  mm at day 9 and this was significantly different to that of 5.0 mg/ml which was  $48.0 \pm 2.0$  mm at day 9.

TABLE 2 shows the effect of crude extracts of *Euphorbia kamerunica* using different solvents on the radial growth of *Aspergillus flavus*. After 24 hours of incubation, only the control and aqueous extract had growth. The ethanol extract did not grow until day 3. At day 9, the least radial growth was observed for diethyl ether which was  $31.5 \pm 0.5$  mm at concentration of 2.5 mg/ml and  $33.5 \pm 0.5$  mm at 5.0 mg/ml and these values

were not significantly different from each other but significantly different from the control. TABLE 3 shows the effect of crude extracts of *E. kamerunica* plant using different solvents on the radial growth of *Microsporium audouinii*. For ethyl acetate extract, there was no growth recorded throughout the period of the experiment at concentrations of 2.5 mg/ml and 5.0 mg/ml. This showed that the extract inhibited the growth of the organism. For the ethanol extract, growth was not observed until day 8. At concentration of 2.5 mg/ml, the radial growth was  $17.0 \pm 0.0$  mm and  $14.5 \pm 0.5$  mm at 5.0 mg/ml. The values for the ethanol extract at these two concentrations were not significantly different on day 9 but they were significantly different to the value obtained for the control. The radial growth was  $24.0 \pm 0.0$  mm at concentration of 2.5 mg/ml and  $23.0 \pm 2.0$  mm at 5.0 mg/ml.

The effect of crude extracts of *Euphorbia kamerunica* plant using different solvents on the radial growth of *Microsporium canis* var. *distortum* is shown in TABLE 4. At day 4, there was no growth for methanol extract at 5.0 mg/ml and ethanol extract at concentrations of 2.5 and 5.0 mg/ml. At day 5, radial growth was seen at 5.0 mg/ml for methanol extract at  $13.0 \pm 0.0$  mm. The ethanol extract had effect on the organism until day 7 when compared to the other extracts. For the control at day 9, the radial growth was  $88.0 \pm 2.0$  mm and for ethanol extract at the same day, the values were  $23.0 \pm 0.0$  mm and  $21.5 \pm 0.0$  mm at concentrations of 2.5 mg/ml and 5.0 mg/ml respectively. This shows that compared to the control the values were significantly different. This indicates that the ethanol extract had effect on the radial growth of the organism, but the values were not significantly different at both concentrations.

TABLE 5 shows the effect of crude extracts of *Euphorbia kamerunica* plant using different solvents on the radial growth of *Trichophyton mentagrophytes* var. *nodulare*. There were no growths at concentrations of 10.0, 25.0, 50.0 and 100.0 mg/ml. No growth was observed until day 4 for ethanol extract. The values were not significantly different at concentrations of 2.5 mg/ml and 5.0 mg/ml which were  $16.5 \pm 0.5$  mm and  $14.0 \pm 0.0$  mm respectively but when compared to the control, they were significantly different.

At day 9, the dichloromethane extract showed the least radial growth values and these values were significantly different from each other and from the control. The values were  $58.5 \pm 1.5$  mm at concentration of 2.5 mg/ml and  $50.5 \pm 0.5$  mm at 5 mg/ml and for the control, it was 90.0 mm.

All the extracts used inhibited the growth of all the fungi at concentrations between 10.0mg/ml and 100.0mg/ml. Growth was observed at concentrations of 2.5 mg/ml and 5.0 mg/ml.

The extracts of *Euphorbia kamerunica* showed activities against the radial growth of fungi and dermatophytes used. There were variations in the activities of the different solvents used for extraction. Ethyl acetate extract of the plant totally inhibited the growth of *Microsporium audouinii* throughout the period of the experiment. [24] carried out a study on the plants used in Guatemala for the treatment of dermatophytic infection and their results were consistent with this study. [10] worked on 44 aqueous plant extracts and 22 out of them inhibited the growth of one or more dermatophytes including *Microsporium canis* and *Trichophyton mentagrophytes* which also in agreement with the work done here in that these extracts had activities on dermatophytes. Study carried out by [25] on crude extracts of *Erigeron floribundus* showed broad spectrum against *Microsporium canis*, *Microsporium gypseum*, *Trichophyton mentagrophytes*, *Epidermophyton floccosum*. This is also in agreement with this study where antifungal activities were observed with extracts of *Euphorbia kamerunica* on *Microsporium canis* and *Trichophyton mentagrophytes*.

#### **IV. Conclusion**

From this experiment, some of the crude extracts of *Euphorbia kamerunica* plant were effective against the growth of some dermatophytes from day 6 of the experiment through to the end at concentrations of 2.5mg/ml and 5mg/ml. Further work needs to be carried out on the isolation of the compounds to know the active ones against these microorganisms, after which they might be used as treatment for infections caused by dermatophytes.
